oligonucleotide, but that there is no disruption in the progression of base-paired nucleotides in the resulting duplex. When short strands of nucleic acid align contiguously along a longer strand the hybridization of each is stabilized by the hybridization of the neighboring fragments because the basepairs can stack along the helix as though the backbone was in fact uninterrupted. This cooperativity of binding can give each segment a stability of interaction in excess of what would be expected for the segment hybridizing to the longer nucleic acid alone. One application of this observation has been to assemble primers for DNA sequencing, typically about 18 nucleotides long, from sets of three hexamer oligonucleotides that are designed to hybridize in this way [Kotler, L.E., *et al.* (1993) Proc. Natl. Acad. Sci. USA 90:4241]. The resulting doubly-nicked primer can be extended enzymatically in reactions performed at temperatures that might be expected to disrupt the hybridization of hexamers, but not of 18-mers.

The use of composite or split oligonuceotides is applied with success in the Invader™-directed cleavage assay. The probe oligonucleotide may be split into two oligonucleotides which anneal in a contigious and adjacent manner along a target oligonucleotide as diagrammed in Figure 68. In this figure, the downstream oligonucleotide (analogous to the probe of Figure 29) is assembled from two smaller pieces: a short segment of 6-10 nts (termed the "miniprobe"), that is to be cleaved in the course of the detection reaction, and an oligonucleotide that hybridizes immediately downstream of the miniprobe (termed the "stacker"), which serves to stabilize the hybridization of the probe. To form the cleavage structure, an upstream oligonucleotide (the "Invader™" oligo) is provided to direct the cleavage activity to the desired region of the miniprobe. Assembly of the probe from non-linked pieces of nucleic acid (*i.e.*, the miniprobe and the stacker) allows regions of sequences to be changed without requiring the re-synthesis of the entire proven sequence, thus improving the cost and flexibility of the detection system. In addition, the use of unlinked composite oligonucleotides makes the system more stringent in its requirement of perfectly matched hybridization to achieve signal generation, allowing

this to be used as a sensitive means of detecting mutations or changes in the target nucleic acid sequences.

As illustrated in Figure 68, in one embodiment, the methods of the present invention employ at least three oligonucleotides that interact with a target nucleic acid to form a cleavage structure for a structure-specific nuclease. More specifically, the cleavage structure comprises i) a target nucleic acid that may be either single-stranded or double-stranded (when a double-stranded target nucleic acid is employed, it may be rendered single-stranded, *e.g.*, by heating); ii) a first oligonucleotide, termed the "stacker," which defines a first region of the target nucleic acid sequence by being the complement of that region (region W of the target as shown in Fig. 67); iii) a second oligonucleotide, termed the "miniprobe," which defines a second region of the target nucleic acid sequence by being the complement of that region (regions X and Z of the target as shown in Fig. 67); iv) a third oligonucleotide, termed the "invader," the 5' part of which defines a third region of the same target nucleic acid sequence (regions Y and X in Fig. 67), adjacent to and downstream of the second target region (regions X and Z), and the second or 3' part of which overlaps into the region defined by the second oligonucleotide (region X depicts the region of overlap). The resulting structure is diagrammed in Figure 68.

While not limiting the invention or the instant discussion to any particular mechanism of action, the diagram in Figure 68 represents the effect on the site of cleavage caused by this type of arrangement of three oligonucleotides. The design of these three oligonucleotides is described below in detail. In Figure 68, the 3' ends of the nucleic acids (*i.e.*, the target and the oligonucleotides) are indicated by the use of the arrowheads on the ends of the lines depicting the strands of the nucleic acids (and where space permits, these ends are also labelled "3'"). It is readily appreciated that the three oligonucleotides (the invader, the miniprobe and the stacker) are arranged in a parallel orientation relative to one another, while the target nucleic acid strand is arranged in an anti-parallel orientation relative to the three oligonucleotides. Further it is clear that the invader oligonucleotide is located upstream of the miniprobe oligonucleotide and that the miniprobe olignuceotide is located upstream of the stacker

oligonucleotide and that with respect to the target nucleic acid strand, region W is upstream of region Z, region Z is upstream of upstream of region X and region X is upstream of region Y (that is region Y is downstream of region X, region X is downstream of region Z and region Z is downstream of region W). Regions of complementarity between the opposing strands are indicated by the short vertical lines. While not intended to indicate the precise location of the site(s) of cleavage, the area to which the site of cleavage within the miniprobe oligonucleotide is shifted by the presence of the invader oligonucleotide is indicated by the solid vertical arrowhead. Figure 68 is not intended to represent the actual mechanism of action or physical arrangement of the cleavage structure and further it is not intended that the method of the present invention be limited to any particular mechanism of action.

It can be considered that the binding of these oligonucleotides divides the target nucleic acid into four distinct regions: one region that has complementarity to only the stacker (shown as "W"); one region that has complemetarity to only the miniprobe (shown as "Z"); one region that has complementarity only to the Invader™ oligo (shown as "Y"); and one region that has complementarity to both the Invader™ and miniprobe oligonucleotides (shown as "X").

In addition to the benefits cited above, the use of a composite design for the oligonucleotides which form the cleavage structure allows more latitude in the design of the reaction conditions for performing the Invader™-directed cleavage assay. When a longer probe (*e.g.*, 16-25 nt), as described in section III above, is used for detection in reactions that are performed at temperatures below the T_m of that probe, the cleavage of the probe may play a significant role in destabilizing the duplex of which it is a part, thus allowing turnover and reuse of the recognition site on the target nucleic acid. In contrast, with miniprobes, reaction temperatures that are at or above the T_m of the probe mean that the probe molecules are hybridizing and releasing from the target quite rapidly even without cleavage of the probe. When an upstream Invader™ oligonucleotide and a cleavage means are provided the miniprobe will be specifically cleaved, but the cleavage will not be necessary to the turnover of the miniprobe. If a long probe (*e.g.*, 16-25 nt) were to be used in this way the
